Prior spontaneous preterm birth No h/o of preterm birth, but short cervix (≤2cm at ≤24 wk)	Needs Progesterone?								

Aspirin for Preeclampsia Prevention (ACOG Committee Opinion 743, July 2018):

Table 1. Clinical Risk Assessment for Preeclampsia*

Risk Level	Risk Factors	Recommendation
High ¹	<ul style="list-style-type: none"> • History of preeclampsia, especially when accompanied by an adverse outcome • Multifetal gestation • Chronic hypertension • Type 1 or 2 diabetes • Renal disease • Autoimmune disease (systemic lupus erythematosus, antiphospholipid syndrome) 	Recommend low-dose aspirin if the patient has one or more of these high-risk factors
Moderate ²	<ul style="list-style-type: none"> • Nulliparity • Obesity (body mass index greater than 30) • Family history of preeclampsia (mother or sister) • Sociodemographic characteristics (African American race, low socioeconomic status) • Age 35 years or older • Personal history factors (eg, low birthweight or small for gestational age, previous adverse pregnancy outcome, more than 10-year pregnancy interval) 	Consider low-dose aspirin if the patient has more than one of these moderate-risk factors ³
Low	<ul style="list-style-type: none"> • Previous uncomplicated full-term delivery 	Do not recommend low-dose aspirin

Absolute Contraindications: aspirin allergy, hypersensitivity to other salicylates/NSAIDs, nasal polyps (life-threatening bronchoconstriction), asthmatics with history of aspirin induced acute bronchospasm

Relative Contraindications: history of GI bleed, active PUD, other sources of GI or GU bleeding, severe hepatic dysfunction, <18 yo and recovering from viral illness (Reye syndrome risk)

Timing: Optimal when started before 16 weeks but should be initiated between 12 to 28 weeks and continued until delivery.

Low-Dose Aspirin Use During Pregnancy

Reference: ACOG Committee Opinion, No. 742, July 2018

Recommendations

The American College of Obstetricians and Gynecologists (ACOG) and the Society for Maternal-Fetal Medicine make the following recommendations:

- **Low-dose aspirin (81 mg/day) prophylaxis is recommended in women at high risk of preeclampsia and should be initiated between 12 weeks and 28 weeks of gestation (optimally before 16 weeks) and continued daily until delivery.**
- Low-dose aspirin prophylaxis should be considered for women with more than one of several moderate risk factors for preeclampsia.
- Low-dose aspirin prophylaxis is not recommended solely for the indication of prior unexplained stillbirth, in the absence of risk factors for preeclampsia.
- Low-dose aspirin prophylaxis is not recommended for prevention of fetal growth restriction, in the absence of risk factors for preeclampsia.
- Low-dose aspirin prophylaxis is not recommended for the prevention of spontaneous preterm birth, in the absence of risk factors for preeclampsia.
- Low-dose aspirin prophylaxis is not recommended for the prevention of early pregnancy loss.

Preeclampsia Risk Factors

High-Risk Factors (Recommend prophylactic low-dose aspirin if any of these risk factors are present):

- Preeclampsia in a previous pregnancy
- Multifetal pregnancy
- Chronic hypertension (high blood pressure)
- Diabetes (type 1 or type 2)
- Kidney disease
- Autoimmune disorder (lupus, rheumatoid arthritis, etc.)
- Antiphospholipid or anticardiolipin syndrome

Moderate-Risk Factors (Consider prophylactic low-dose aspirin if more than 1 of these factors are present):

- Nulliparity
- Obesity (body mass index 30 kg/m² or greater)
- Mother or sister had preeclampsia
- African ancestry (based on patient self-report)
- Low socioeconomic status
- Maternal age 35 years or older
- Patient born with low birthweight or small-for-gestational age
- Previous pregnancy with small-for-gestational age or other adverse outcome
- Interpregnancy interval more than 10 years
